Problem 1:

(Prove: The real 2x2 matrix blah represents a complex-linear map iff a=d, c=-b

Let the real matrix $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ represent a complex-linear map. Then we have:

$$i \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = i \begin{bmatrix} b \\ d \end{bmatrix} = \begin{bmatrix} -d \\ b \end{bmatrix}$$

And also

$$i \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} -1 \\ 0 \end{bmatrix}$$
$$= \begin{bmatrix} -a \\ -c \end{bmatrix}$$

So $\begin{bmatrix} -d \\ b \end{bmatrix} = \begin{bmatrix} -a \\ -c \end{bmatrix}$; that is, a = d and b = -c. Now, let the real matrix A have that a = d and c = -b. Write $A = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$, and let T be the linear map associated with A. Also, let \vec{z} be the vector associated with z, for any $z \in \mathbb{C}$.

Let $z = x + iy, w = x' + iy' \in \mathbb{C}$. Then:

$$T(wz) = A\overline{wz}$$

$$= \begin{bmatrix} a & b \\ -b & a \end{bmatrix} \begin{bmatrix} xx' - yy' \\ xy' + yx' \end{bmatrix}$$

$$= \begin{bmatrix} a(xx' - yy') + b(xy' + yx') \\ a(xy' + yx') - b(xx' - yy') \end{bmatrix}$$

$$= \begin{bmatrix} x' \\ y' \end{bmatrix} \times \begin{bmatrix} ax + by \\ ax - by \end{bmatrix}$$

$$= \overrightarrow{w} \times T(\overrightarrow{z})$$

(with \times being complex multiplication).

That is, A's associated linear map is \mathbb{C} -linear.

So, we have that the real matrix $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ represents a complex-linear map if and only if a = d and b = -c.

Problem 2:

Consider $\int_{-\pi} \overline{z}^n dz$. Define $\alpha : [0, 2\pi] \to \mathbb{C}$ by $\alpha(t) = R(\cos(t) + i\sin(t))$.

If $n \neq 1$, we have

$$\begin{split} \int\limits_{|z|=R} \overline{z}^n dz &= \int\limits_{\alpha} \overline{z}^n dz \\ &= \int\limits_{0}^{2\pi} [R(\cos(t) - i\sin(t))]^n [R(-\sin(t) + i\cos(t))] dt \\ &= R^{n+1} \int\limits_{0}^{2\pi} \frac{-\sin(t) + i\cos(t)}{(\cos(t) + i\sin(t))^n} dt \\ &= R^{n+1} \frac{1}{n-1} [((\cos(2\pi) + i\sin(2\pi)))^{1-n} - (\cos(0) + i\sin(0))^{1-n} \\ &= R^{n+1} \frac{1}{n-1} [1 - 1] \\ &= 0 \end{split}$$

(Here, we're using freely the fact that $\overline{z} = 1/z$ if |z| = 1, and we gloss over the *u*-substitution with $u = \cos(t) + i\sin(t)$.)

And if n = 1, we have

$$\int_{|z|=R} \overline{z}^n dz = \int_{\alpha} \overline{z} dz$$

$$= \int_{0}^{2\pi} [R(\cos(t) - i\sin(t))][R(-\sin(t) + i\cos(t))]dt$$

$$= R^2 \int_{0}^{2\pi} \frac{-\sin(t) + i\cos(t)}{\cos(t) + i\sin(t)} dt$$

$$= R^2 \int_{0}^{2\pi} i \frac{\cos(t) + i\sin(t)}{\cos(t) + i\sin(t)} dt$$

$$= R^2 \int_{0}^{2\pi} i dt$$

$$= R^2 2\pi i$$

Problem 3:

Let $D \subset \mathbb{C}$ be open, and let D^* be D's reflection about the x-axis. Let $f \in \mathcal{O}(D)$, and define $g(z) = \overline{f(\overline{z})}$. As an intermediate step, define $h(z) = f(\overline{z})$.

Let f = u + iv. Then h((x, y)) = f((x, -y)); say that h = u' + iv'. Also, $u_x(z) = v_y(z)$ for all $z \in \mathbb{C}$.

Moreover, $u_y(z) = -v_x(z)$ for all $z \in \mathbb{C}$. So

(I remember someone saying something about more problems but I must be missing one...:/)
